## GRADO EN INGENIERÍA NAVAL Y OCEÁNICA TRABAJO FIN DE GRADO

*CURSO 2.020-2021*

**PROYECTO NÚMERO** 2021-GENO-25

**TIPO DE BUQUE:** Buque arrastrero congelador 1500m3.

**CLASIFICACIÓN, COTA Y REGLAMENTOS DE APLICACIÓN:** Bureau Veritas. Torremolinos, MARPOL.PARA ZONAS POLARES.

**CARACTERÍSTICAS DE LA CARGA:** Volumen de bodega de 1500 m<sup>3</sup>. Bodegas y entrepuentes de carga.

**VELOCIDAD Y AUTONOMÍA:** 12 nudos en condiciones de servicio, 85% MCR Y 10 % margen de mar. 40 días de autonomía.

**SISTEMAS Y EQUIPOS DE CARGA / DESCARGA:** Los propios de este tipo de buques.

**PROPULSIÓN:** Motor diésel acoplado a hélice de paso fijo.

**TRIPULACIÓN Y PASAJE:** 32 tripulantes.

**OTROS EQUIPOS E INSTALACIONES:** Hélice transversal de proa y los habituales en este tipo de buques.

## 2 PRESENTACIÓN

En el presente cuaderno vamos a estudiar las 6 condiciones de carga más representativas de nuestro buque.

En primer lugar, la condición de salida de puerto y llegada a caladero, y después estudiaremos la salida de caladero y la llegada a puerto tanto si ha sido una buena marea y el buque trae las bodegas llenas; como si ha sido una mala marea y estas vienen al 20% de su capacidad.

Para llegar a estas condiciones, primero tenemos que determinar los pesos que tenemos a bordo, como pueden ser el peso en rosca, el peso de los víveres, tripulación, pertrechos, etc.

A continuación, recordaremos los tanques que diseñamos en el cuaderno 4, y estudiamos cuales de estos tanques presentan correcciones por superficies libres. Aplicaremos estas correcciones cuando sea necesario: para los tanques que presentan un llenado o vaciado de una condición a otra, y dentro de estos tanques, para todos los de lastre y para el peor de cada consumidor.

Llenaremos o vaciaremos estos tanques según la condición a estudiar y comprobaremos el calado del buque, el trimado, el GM y si cumple o no los criterios de estabilidad, que explicamos también en este cuaderno.

Se anexarán los informes de salida de Maxsurf de todas las condiciones estudiadas.

### 3 CRITERIOS DE ESTABILIDAD Y CONDICIONES DE CARGA APLICABLES

La sociedad clasificadora del buque proyecto será el Bureau Veritas, así que, además de cumplir con sus requerimientos, tenemos que cumplir la normativa dada en el *Convenio de Torremolinos, 1993*, (mismos requisitos que en el *International Code of Intact Stability, Código IS 2008*, pero este último no es aplicable a buques de pesca).

#### 3.1 Código internacional de estabilidad sin avería (Código IS CODE 2008) y Convenio de Torremolinos

En ambos reglamentos encontramos los mismos requerimientos:

##### 3.1.2. Criterios generales recomendados

3.1.2.1. *El área situada bajo la curva de brazos adrizantes no será inferior a 0.055 m·rad hasta el ángulo de escora de 30° ni inferior a 0.090 m·rad hasta 40° o hasta el ángulo de inundación  $\Theta$  si éste es inferior a 40°. Además, el área situada bajo la curva de brazos adrizantes entre los ángulos de escora de 30° y 40°, o entre los ángulos de 30° y  $\Theta$  si éste es menor de 40°, no será inferior a 0.030 m·rad..  $\Theta$  es el ángulo de escora en que las aberturas del casco, la superestructura o las casetas que no se puedan cerrar rápidamente de modo estanco a la intemperie, comienzan a quedar inmersas. En la aplicación de este criterio no es necesario considerar abiertas las pequeñas aberturas a través de las cuales pueden producirse una inundación progresiva. En caso de que la estabilidad dinámica a 30° fuesen inferior a 0.065 m·rad, deberemos aplicar el criterio de viento y agua en cubierta.*

3.1.2.2. *El brazo adrizante GZ será de 0,2m como mínimo para un ángulo de escora de igual o superior a 30°.*

3.1.2.3 *El brazo adrizante máximo  $GZ_{\text{máx}}$  corresponderá a un ángulo de escora preferiblemente superior a 30° pero nunca inferior a 25°.*

3.1.2.4 *.La altura metacéntrica inicial GM no será inferior a 0,15m.*

##### 4.2.3. Criterios generales recomendados:

4.2.3.1. *Los criterios generales de estabilidad sin avería que figuran en 3.1.2 se aplicarán a los buques pesqueros de eslora igual o superior a 42m, con salvedad de las prescripciones sobre la altura metacéntrica inicial GM, en el caso de buques pesqueros de una sola cubierta no será inferior a 0,35m. En buques de superestructura corrida cuya eslora sea igual o superior a 70m, la altura metacéntrica podrá reducirse a un valor que sea satisfactorio a juicio de la Administración, pero en ningún caso inferior a 0,15m.*

4.2.3.2. *La adopción por los países de criterios simplificados para aplicar estos valores básicos de estabilidad a sus propios tipos y clases de buques se reconoce como un método práctico y valioso para evaluar la estabilidad de modo rentable.*

*4.2.3.3. Cuando se utilicen dispositivos que no sean quillas de balance para limitar el ángulo de balance, la Administración habrá de quedar satisfecha de que se observan los criterios de estabilidad mencionados en 4.2.3.1 en todas las condiciones operaciones.*

### **3.2 Resumen criterios de estabilidad:**

Área curva GZ de  $0^\circ$  a  $30^\circ \geq 0.055 \text{ m} \cdot \text{rad}$  + viento + agua embarcada

Área curva GZ de  $0^\circ$  a  $40^\circ$  ó  $\Theta \geq 0.090 \text{ m} \cdot \text{rad}$

Área curva GZ de  $30^\circ$  a  $40^\circ$  ó  $\Theta \geq 0.030 \text{ m} \cdot \text{rad}$

GZ a  $30^\circ$  o superior  $\geq 0.200 \text{ m} \cdot \text{rad}$ .

Ángulo de GZ máximo  $\geq 25^\circ$

GM inicial  $\Theta \geq 0.35 \text{ m}$  ( $>0.15 \text{ m}$  en buques de 2 cubiertas o con LPP  $>70 \text{ m}$ ) En nuestro caso tenemos dos cubiertas completas, por lo que  $Gm \Theta \geq 0.5 \text{ m}$

Adjuntamos captura de los criterios introducidos en Maxsurf:

### 3.3 Criterio meteorológico

El criterio meteorológico viene expuesto en el IS Code 2008. A continuación se adjuntan extractos de *Disposición 5295 del BOE núm. 70 de 2011*.

#### 2.3 Criterio de viento y balance intensos (criterio meteorológico)

2.3.1 Habrá que demostrar la aptitud del buque para resistir los efectos combinados del viento de través y del balance, con referencia a la figura 2.3.1, del modo siguiente:

- .1 se someterá el buque a la presión de un viento constante que actúe perpendicularmente al plano de crujía, lo que dará como resultado el correspondiente brazo escorante ( $l_{w1}$ );
- .2 se supondrá que a partir del ángulo de equilibrio resultante ( $\varphi_0$ ), el buque se balancea por la acción de las olas hasta alcanzar un ángulo de balance ( $\varphi_1$ ) a barlovento. El ángulo de escora provocado por un viento constante ( $\varphi_0$ ) no deberá ser superior a  $16^\circ$  o al 80 % del ángulo de inmersión del borde de la cubierta, si este ángulo es menor;
- .3 a continuación se someterá al buque a la presión de una ráfaga de viento que dará como resultado el correspondiente brazo escorante ( $l_{w2}$ ); y
- .4 en estas circunstancias, el área  $b$  debe ser igual o superior al área  $a$ , como se indica en la figura 2.3.1 *infra*:

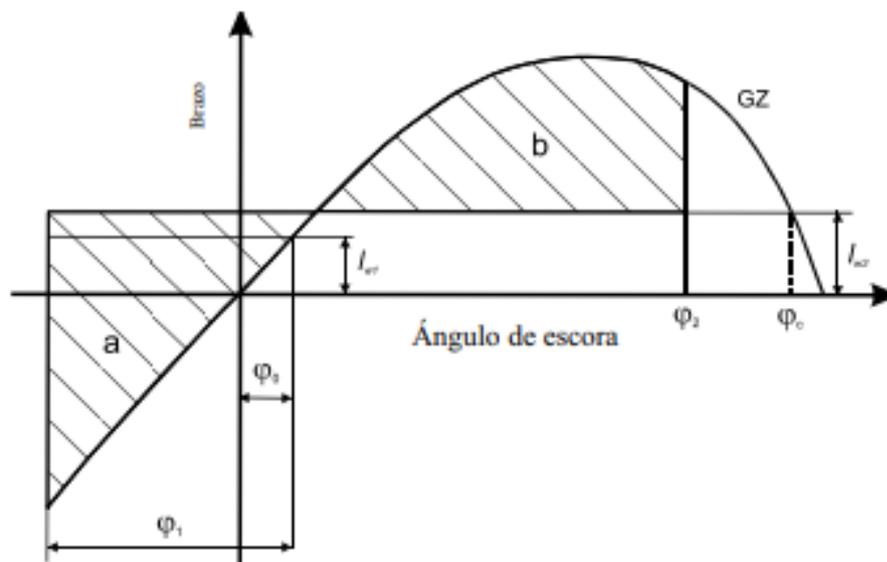

Figura 2.3.1: Viento y balance intensos

donde los ángulos de la figura 2.3.1 se definen del modo siguiente:

$\phi_0$  = ángulo de escora provocado por un viento constante

$\phi_1$  = ángulo de balance a barlovento debido a la acción de las olas (véanse 2.3.1.2, 2.3.4 y la nota a pie de página)

$\phi_2$  = ángulo de inundación descendente ( $\phi_r$ ), o  $50^\circ$ , o  $\phi_c$ , tomando de estos valores el menor,

siendo:

$\phi_r$  = ángulo de escora al que se sumergen las aberturas del casco, superestructuras o casetas que no puedan cerrarse de modo estanco a la intemperie. Al aplicar este criterio no hará falta considerar abiertas las pequeñas aberturas por las que no pueda producirse inundación progresiva

$\phi_c$  = ángulo de la segunda intersección entre la curva de brazos escorantes  $l_{w2}$  y la de brazos GZ.

2.3.2 Los brazos escorantes  $l_{w1}$  y  $l_{w2}$  provocados por el viento, a que se hace referencia en 2.3.1.1 y 2.3.1.3, son valores constantes a todos los ángulos de inclinación y se calcularán del modo siguiente:

$$l_{w1} = \frac{P \cdot A \cdot Z}{1000 \cdot g \cdot \Delta} \quad (m) \quad y$$

$$l_{w2} = 1,5 \cdot l_{w1} \quad (m)$$

donde:

$P$  = presión del viento de 504 Pa. El valor de  $P$  utilizado para los buques en servicio restringido podrá reducirse a reserva de que lo apruebe la Administración

$A$  = área lateral proyectada de la parte del buque y de la cubertada que quede por encima de la flotación ( $m^2$ )

$Z$  = distancia vertical desde el centro del área  $A$  hasta el centro del área lateral de la obra viva, o aproximadamente hasta el punto medio del calado medio (m)

$\Delta$  = desplazamiento (t)

$g$  = aceleración debida a la gravedad de  $9,81 \text{ m/s}^2$ .

2.3.3 Si la Administración los considera satisfactorios, podrán aceptarse otros medios para determinar el brazo escorante ( $l_{w0}$ ) como alternativa equivalente al cálculo que figura en 2.3.2. Cuando se realicen dichas pruebas alternativas, se hará referencia a las Directrices elaboradas por la Organización.<sup>2</sup> La velocidad del viento utilizada en las pruebas será igual a 26 m/s en tamaño natural con un perfil de la velocidad uniforme. El valor de la velocidad del viento utilizado para los buques en servicios restringidos podrá reducirse a un valor que la Administración considere satisfactorio.

2.3.4 El ángulo de balance ( $\phi_1$ )<sup>3</sup> a que se hace referencia en 2.3.1.2 se calculará del modo siguiente:

$$\phi_1 = 109 \cdot k \cdot X_1 \cdot X_2 \cdot \sqrt{r \cdot s} \quad (\text{grados})$$

donde:

$X_1$  = factor indicado en el cuadro 2.3.4-1

$X_2$  = factor indicado en el cuadro 2.3.4-2

$k$  = factor que corresponde a lo siguiente:

$k$  = 1,0 respecto de un buque de pantoque redondo que no tenga quillas de balance ni quilla de barra

$k$  = 0,7 respecto de un buque de pantoque quebrado

$k$  = el valor que se indica en el cuadro 2.3.4-3 respecto de un buque con quillas de balance, quilla de barra o ambas

$$r = 0,73 + 0,6 \text{ OG}/d$$

donde:

$$\text{OG} = \text{KG} - d$$

$$d = \text{calado medio de trazado del buque (m)}$$

$s$  = factor indicado en el cuadro 2.3.4-4, donde  $T$  es el periodo natural de balance del buque. Si no se dispone de información suficiente, puede utilizarse la siguiente aproximación:

$$\text{Periodo de balance} \quad T = \frac{2 \cdot C \cdot B}{\sqrt{GM}} (s)$$

donde:

$$C = 0,373 + 0,023(B/d) - 0,043(L_{\text{rot}}/100)$$

Los símbolos que aparecen en los cuadros 2.3.4-1, 2.3.4-2, 2.3.4-3 y 2.3.4-4 y en la fórmula del periodo de balance tienen los siguientes significados:

$L_{\text{rot}}$  = eslora en la flotación del buque (m)

$B$  = manga de trazado del buque (m)

$d$  = calado medio de trazado del buque (m)

$C_B$  = coeficiente de bloque (-)

$A_k$  = área total de las quillas de balance o área de la proyección lateral de la quilla de barra, o suma de estas áreas (m<sup>2</sup>)

GM = altura metacéntrica corregida por el efecto de superficie libre (m).

**Cuadro 2.3.4-1: Valores del factor  $X_1$**

| $B/d$      | $X_1$ |
|------------|-------|

| $\leq 6$  | 0,100 |
| 7         | 0,098 |
| 8         | 0,093 |
| 12        | 0,065 |
| 14        | 0,053 |
| 16        | 0,044 |
| 18        | 0,038 |
| $\geq 20$ | 0,035 |

(Los valores intermedios en los cuadros 1-4 se obtendrán por interpolación lineal)

2.3.5 Los cuadros y fórmulas descritos en 2.3.4 se basan en datos de buques que presentan las siguientes características:

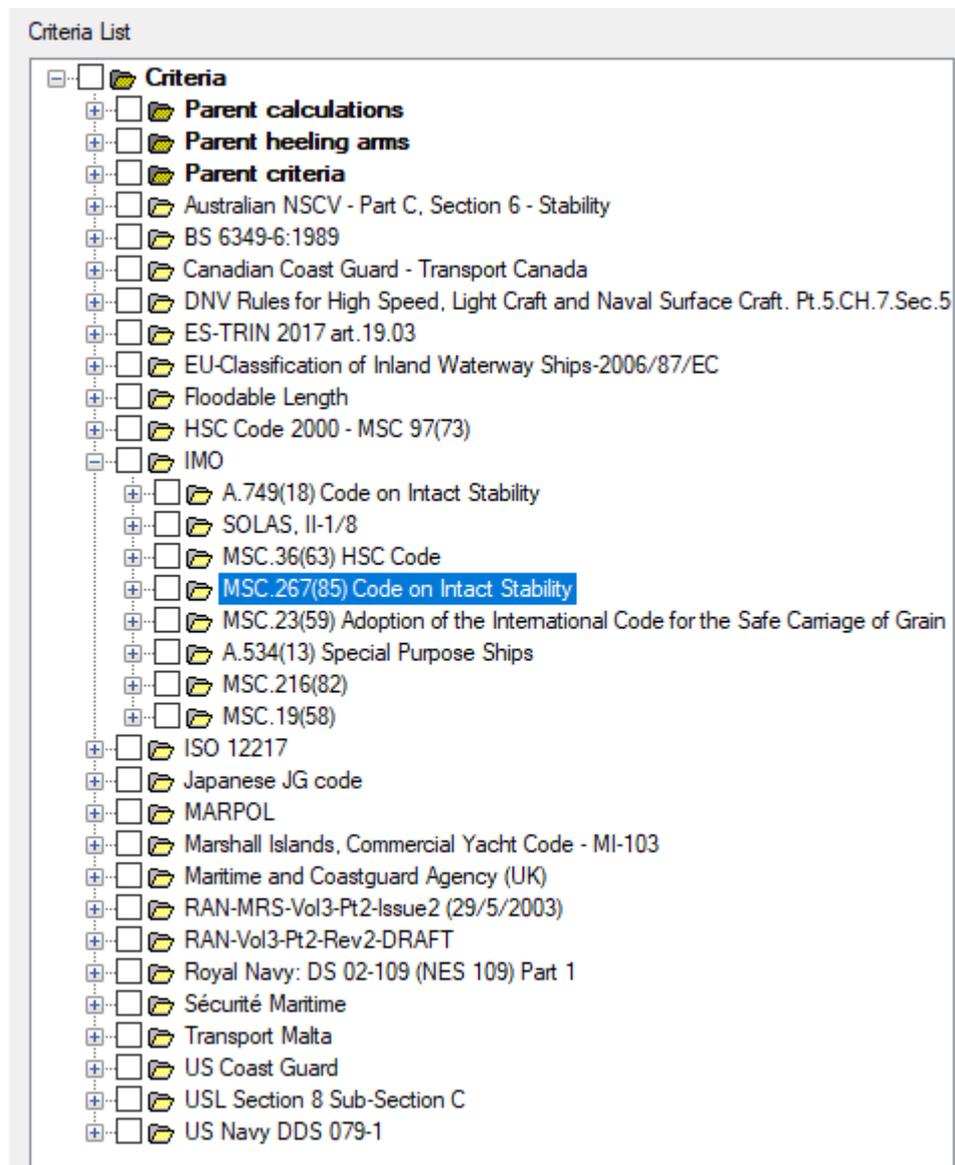

- .1  $B/d$  inferior a 3,5;
- .2  $(KG/d-1)$  entre -0,3 y 0,5; y
- .3  $T$  inferior a 20 s.

En el caso de los buques cuyos parámetros rebasen los límites indicados *supra*, el ángulo de balance ( $\varphi_1$ ) podrá determinarse también mediante experimentos con un modelo de buque de ese tipo utilizando el procedimiento descrito en la circular MSC.1/Circ.1200. Asimismo, la Administración podrá aceptar las estimaciones alternativas mencionadas para cualquier buque si lo estima oportuno.

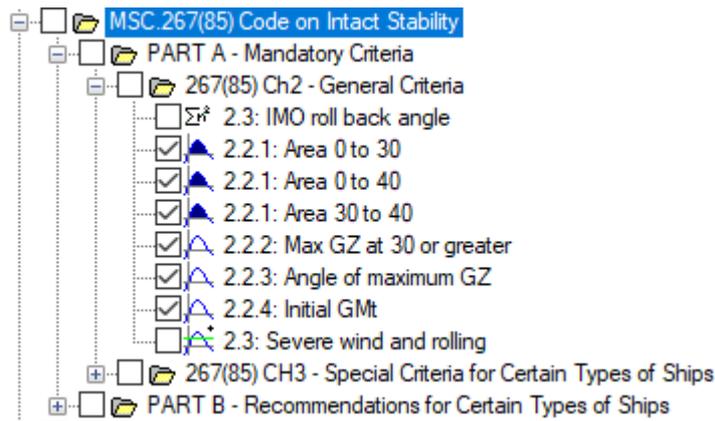

### 3.4 Criterios de estabilidad en Maxsurf

Ahora procedemos a introducir los criterios mencionados en el apartado correspondiente de Maxsurf, para después estudiar si se cumplen o no en cada condición.

En “criteria” tenemos la siguiente reglamentación a aplicar:

Escogemos el MSC 267 (85), que equivale al IS CODE 2008, cuyos criterios son los siguientes:

Para cada criterio:

-GZ a 30° o superior  $\geq 0.200 \text{ m} \cdot \text{rad}$ .

|    |                                     | 267(85) Ch2 - General Criteria<br>2.2.2: Max GZ at 30 or greater | Value  | Units |
|----|-------------------------------------|--|--------|-------|
| 1  | <input type="checkbox"/>            | in the range from the greater of                                 |        |       |
| 2  | <input checked="" type="checkbox"/> | spec. heel angle   | 30,0   | deg   |
| 3  | <input type="checkbox"/>            | angle of equilibrium   |        | deg   |
| 4  | <input type="checkbox"/>            | to the lesser of   |        |       |
| 5  | <input checked="" type="checkbox"/> | spec. heel angle   | 90,0   | deg   |
| 6  | <input type="checkbox"/>            | spec. angle above equilibrium                                    | 0,0    | deg   |
| 7  | <input type="checkbox"/>            | angle of first GZ peak   |        | deg   |
| 8  | <input checked="" type="checkbox"/> | angle of max. GZ   |        | deg   |
| 9  | <input type="checkbox"/>            | first flooding angle of the                                      | Downfl | deg   |
| 10 | <input type="checkbox"/>            | shall not be less than ( $\geq$ )                                | 0,200  | m     |

-Ángulo de GZ máximo  $\geq 25^\circ$

|   |                          | 267(85) Ch2 - General Criteria<br>2.2.3: Angle of maximum GZ | Value  | Units |
|---|--------------------------|--|--------|-------|
| 1 | <input type="checkbox"/> | limited by first GZ peak angle                               |        | deg   |
| 2 | <input type="checkbox"/> | first flooding angle of the                                  | Downfl | deg   |
| 3 | <input type="checkbox"/> | shall not be less than ( $\geq$ )                            | 25,0   | deg   |

-GM inicial  $\Theta \geq 0.35 \text{ m}$  ( $>0.15 \text{ m}$  en buques de 2 cubiertas o con LPP  $>70 \text{ m}$ ) En nuestro caso tenemos dos cubiertas completas, por lo que  $Gm \Theta \geq 0.15 \text{ m}$

## 4 PESO MUERTO

En esta partida incluimos todos los pesos del buque que no pertenecen a su peso en rosca, que vienen siendo los consumos, el peso de la tripulación con sus pertenencias, pertrechos, víveres, la carga en las bodegas y equipos específicos del buque como pueden ser las redes de pesca.

### 4.1 Consumos al 100%

Los consumos del buque son unos pesos variables, ya que dependen de los días de navegación que lleve el buque, también lo son por ejemplo los víveres, que se van consumiendo conforme avanza la campaña. Por eso calcularemos el peso de los consumos al 100% y al 10%, que serán las condiciones de salida de puerto y de vuelta.

Dentro de estos consumos podemos distinguir entre los combustibles del buque (MDO y HFO), agua dulce, aceite, lodos y aguas negras principalmente. Adjuntamos una primera captura del Maxsurf donde se muestra el peso de estos consumos al 100% de su capacidad:

#### 4.1.1 Combustible al 100%

Se adjunta captura de los tanques introducidos en Maxsurf

El peso total de los consumos al 100% será entonces de 1031 t.

## 4.2 Consumos al 10%

Adjuntamos captura de cada partida que constituye los consumos, en este caso al 10% de capacidad.

### 4.2.1 Combustible al 10%

El orden de consumo de combustibles es: primero los tanques almacén, después los tanques de sedimentación, y por último los tanques de uso diario.

Entonces, si queda un 10% de la capacidad total de los tanques de MDO del buque, esto significa que solamente queda MDO en los tanques de uso diario, que van al 70%.

Si queda un 10% del volumen de HFO del buque, significa que los tanques de uso diario y sedimentación todavía están llenos, y que se está consumiendo de los tanques HFO 4, que son los últimos tanques almacén de los que se trasiega combustible.

### 4.3 Tripulación

Según el Código IS 2008, se supone un peso de 75kg por pasajero [...] la altura del centro de gravedad de los pasajeros se supondrá igual a 1,0m por encima del nivel de cubierta estando los pasajeros de pie. Además del peso del propio tripulante sumaremos 50 kg de pertenencias, por lo que tenemos un peso total de 125 kg/tripulante

El peso de nuestra tripulación será igual a 4 toneladas y ubicaremos su centro de gravedad en XG=46m y KG=12,3m (en la cubierta castillo bajo).

Introducimos estos datos en el cálculo de pesos:

| Item Name   | Quantity | Unit Mass<br>tonne | Total<br>Mass | Unit<br>Volume | Total<br>Volume | Long.<br>Arm | Trans.<br>Arm | Vert. Arm<br>m |
|-------------|----------|--------------------|---------------|----------------|-----------------|--------------|---------------|----------------|
| Tripulación | 1        | 0,125              | 0,125         |                |                 | 46,000       | 0,000         | 12,300         |

#### 4.4 Pertrechos

Los pertrechos se estiman en función al peso en rosca del buque, siendo un 5% de este peso. Recordamos que, tras los cálculos del cuaderno 2, el peso en rosca del buque es de 1601, por lo que supondremos unos pertrechos de 80t.

| Item Name  | Quantity | Unit Mass<br>tonne | Total<br>Mass | Unit<br>Volume | Total<br>Volume | Long.<br>Arm | Trans.<br>Arm | Vert. Arm<br>m |
|------------|----------|--------------------|---------------|----------------|-----------------|--------------|---------------|----------------|
| Pertrechos | 1        | 80,000             | 80,000        |                |                 | 5,000        | 0,000         | 2,000          |

#### 4.5 Víveres

El peso de los víveres se calcula por el número de tripulantes. En el caso de nuestro buque proyecto tendremos 32 personas a bordo durante 40 días, estimando que la cantidad de víveres necesaria por persona/día es de 4,5kg, tenemos que:

$$\text{Peso víveres} = 4,5 \text{ kg} * 32 \text{ personas} * 40 \text{ días} = 5,8t$$

El centro de gravedad de los víveres se situará en las gambuzas de la cubierta castillo bajo, por lo que XG=42m KG=12.5m.

| Item Name | Quantity | Unit Mass<br>tonne | Total<br>Mass | Unit<br>Volume | Total<br>Volume | Long.<br>Arm | Trans.<br>Arm | Vert. Arm<br>m |
|-----------|----------|--------------------|---------------|----------------|-----------------|--------------|---------------|----------------|
| Víveres   | 1        | 5,800              | 5,800         |                |                 | 42,000       | 0,000         | 12,500         |

#### 4.6 Carga

La carga que llevaremos en nuestra bodegas será pescado blanco congelado y paletizado, cuya densidad es de 0,63t/m3 según *Anexo II (Estabilidad y francobordo), "BOE" núm. 131, de 1 de junio de 2007.*

Para calcular el peso de estas bodegas tenemos que considerar el aislante, que metemos como dato en el factor de densidad (0,97). Multiplicando esta densidad el aislante por la densidad de la carga almacenada tenemos que el factor de densidad a introducir en Maxsurf es:

$$\text{factor densidad} = 0,63 * 0,97 = 0.611t/m3$$

| Name               | Type | Intact<br>Perm. % | Damaged<br>Perm. % | Specific<br>gravity |
|--------------------|------|-------------------|--------------------|---------------------|
| Bodega principal   | Tank | 100               | 100                | 0,611               |
| Bodega entrepuente | Tank | 100               | 100                | 0,611               |

Entonces, el volumen y peso de las bodegas será igual a:

| Item Name            | Quantity    | Unit Mass<br>tonne | Total<br>Mass<br>tonne | Unit<br>Volume<br>m <sup>3</sup> | Total<br>Volume<br>m <sup>3</sup> |
|----------------------|-------------|--------------------|------------------------|----------------------------------|-----------------------------------|
| Bodega principal     | 100%        | 897,050            | 897,050                | 1468,166                         | 1468,166                          |
| Bodega entrepuente   | 100%        | 193,998            | 193,998                | 317,509                          | 317,509                           |
| <b>TOTAL BODEGAS</b> | <b>100%</b> | <b>1091,047</b>    | <b>1091,047</b>        | <b>1785,675</b>                  | <b>1785,675</b>                   |

En este apartado calculamos el volumen total de las bodegas, al 100% de su capacidad, pero las bodegas nunca tendrán el 100% de su volumen ocupado por pescado, ya que dentro de la bodega principal hay escaleras, un tronco de escaleras de salida de emergencia y el hueco del montacargas, además de las carretillas elevadoras. La capacidad máxima que estimaremos para la bodega principal será del 85%, y cuando esta esté al 85%, se llenará la bodega de entrepuente.

#### 4.7 Lastre

El lastre es otro de los pesos variables, en la siguiente captura se mostrará la condición en la que todos los tanques vayan llenos al 100%, pero dependerá del capitán y del libro de estabilidad llenar unos u otros en función de la escora o el asiento del buque, y de lo llenas que vayan las bodegas y los tanques de consumos.

Tenemos un pique de proa y un pique de popa, dividido en tanques de estribor y babor:

| Item Name           | Quantity    | Unit Mass<br>tonne | Total<br>Mass  | Unit<br>Volume | Total<br>Volume |
|---------------------|-------------|--------------------|----------------|----------------|-----------------|
| Pique popa BR       | 100%        | 147,260            | 147,260        | 143,668        | 143,668         |
| Pique popa ER       | 100%        | 147,260            | 147,260        | 143,668        | 143,668         |
| Pique proa          | 100%        | 118,621            | 118,621        | 115,728        | 115,728         |
| <b>TOTAL LASTRE</b> | <b>100%</b> | <b>413,141</b>     | <b>413,141</b> | <b>403,064</b> | <b>403,064</b>  |

#### 4.8 Equipos específicos del buque proyecto

Dentro de esta partida tenemos que introducir el peso de las redes, cables, puertas, maletas, respetos, etc. Se estiman en 35 toneladas y su centro de gravedad se ubicará en XG=58m y KG=9,6m. Recordamos que el local destinado a estibar las artes de pesca se ubica a proa de la cubierta superior.

Se introduce este peso y coordenadas en el programa:

| Item Name      | Quantity | Unit Mass<br>tonne | Total<br>Mass | Unit<br>Volume | Total<br>Volume | Long.<br>Arm | Trans.<br>Arm | Vert. Arm<br>m |
|----------------|----------|--------------------|---------------|----------------|-----------------|--------------|---------------|----------------|
| Artes de pesca | 1        | 35,000             | 35,000        |                |                 | 58,000       | 0,000         | 9,600          |

## 5 PESO EN ROSCA

El peso en rosca del buque proyecto se ha calculado en el cuaderno 2, resultando un peso en rosca de 1601,3 toneladas, margen incluido, cuyo centro de gravedad se ubicará en XG=26,78m y KG=7,55m.

Adjuntamos el cuadro resumen resultante tras el cuaderno 2 para justificar tanto estos pesos como su centro de gravedad.

|                                | Peso (t) | XG(m)  | KG(m)  | MOMX(t-m) | MOMZ(t-m) |
|--------------------------------|----------|--------|--------|-----------|-----------|
| PESO ACEROS                    | 860,810  | 28,700 | 6,450  | 24705,247 | 5552,225  |
| PESO MAQUINARIA PROPULSORA     | 178,030  | 6,579  | 3,915  | 1171,307  | 697,038   |
| PESO OTROS EQUIPOS             | 486,047  | 30,800 | 10,849 | 14970,255 | 5273,229  |
| TOTAL PESO EN ROSCA SIN MARGEN | 1524,887 | 26,787 | 7,556  | 40846,810 | 11522,492 |
| MARGEN 5%                      | 76,244   |        |        |           |           |
| TOTAL PESO EN ROSCA CON MARGEN | 1601,132 |        |        |           |           |

Vemos a continuación los datos del peso en rosca introducidos en Maxsurf, que se corresponden con los resultados del cuaderno 2:

| Item Name     | Quantity | Unit Mass<br>tonne | Total<br>Mass | Unit<br>Volume | Total<br>Volume | Long.<br>Arm | Trans.<br>Arm | Vert. Arm<br>m |
|---------------|----------|--------------------|---------------|----------------|-----------------|--------------|---------------|----------------|
| PESO EN ROSCA | 1        | 1600,000           | 1600,000      |                |                 | 26,800       | 0,000         | 7,500          |

## 6 CORRECCIÓN POR SUPERFICIES LIBRES

En este apartado estudiaremos el movimiento oscilatorio de los líquidos contenidos en los tanques del buque, ya que este movimiento tiene un efecto perjudicial en su estabilidad.

Es inevitable que existan superficies libres en los tanques que contienen fluidos, ya que no pueden ir siempre al 100% o al 0%. Como sabemos que es una situación que se dará durante la navegación, procedemos a explicar cómo corregiremos este momento.

El criterio a aplicar para esta corrección viene dado por el *Código IS 2008*:

- *En todas las condiciones de carga estudiadas, tanto la altura metacéntrica GM como los brazos adrizantes GZ, deben ser corregidos por el efecto de las superficies libres de los tanques.*
- *El efecto de las superficies libres de los tanques, solamente se considera cuando el nivel de llenado se encuentra por debajo del 98%. Por consiguiente, los tanques llenos y los tanques vacíos no corrigen por superficies libres.*
- *Al calcular los efectos de superficie libre de los tanques que contengan líquidos consumibles, se dará por supuesto para cada tipo de líquido, que al menos dos tanques laterales (consumo de tanques simétricos respecto crujía) o un tanque central ofrecen superficies libres, y el tanque o combinación de tanques elegidos será el que presente mayor superficie libre.*
- *No es necesario tener en cuenta los residuos de líquidos que quedan en los tanques vacíos, excepto que esos residuos puedan producir un efecto de superficie libre.*
- *No será necesario incluir en la corrección los tanques pequeños, que a una inclinación de 30° cumplan con la siguiente condición:*

$$\frac{M_{fs}}{\Delta_{min}} < 0.01 \text{ m}$$

$$M_{fs} = v * b * \gamma * k * \sqrt{\delta}$$

$M_{fs}$  = Momento por superficie libre a 30° (ton.m).

$\Delta_{min}$  = Desplazamiento mínimo del buque calculado al calado " $d_{min}$ " (ton).

$d_{min}$  = Calado mínimo del buque sin carga, provisiones al 10% y el mínimo de agua de lastre (m).

$v$  = Capacidad total del tanque ( $m^3$ ).

$b$  = Anchura máxima del tanque (m).

$\gamma$  = Peso específico del líquido contenido en el tanque ( $t/m^3$ ).

$K$  = Coeficiente adimensional indicado en la tabla posterior. Valores intermedios por interpolación.

$\delta = \frac{v}{bh}$  = Coeficiente de bloque del tanque.

$$k = \frac{\sin \theta}{12} \left( 1 + \frac{\tan^2 \theta}{2} \right) \times b/h$$

siendo  $\cot \theta \geq b/h$

$$k = \frac{\cos \theta}{8} \left( 1 + \frac{\tan \theta}{b/h} \right) - \frac{\cos \theta}{12(b/h)^2} \left( 1 + \frac{\cot^2 \theta}{2} \right)$$

siendo  $\cot \theta \leq b/h$

Entonces, la comprobación que tenemos que hacer para un tanque individual sería la siguiente:

$$M_{fs} \text{ 1 tanque} = \frac{v * b * \gamma * k * \sqrt{\delta}}{\Delta_{min}} > 0,01 * \Delta_{min}$$

Y para una pareja de tanques simétricos babor-estribor:

$$M_{fs} \text{ pareja tanques} = \frac{2 * v * b * \gamma * k * \sqrt{\delta}}{\Delta_{min}} > 0,01 * \Delta_{min}$$

Para hallar el valor  $k$ , buscamos la relación  $B/h$  del tanque que se corresponda con 30°, interpolando en los casos que así se requiera:

| $k = \frac{\sin \theta}{12} \left( 1 + \frac{\tan^2 \theta}{2} \right) \times b/h$ siendo $\cot \theta \geq b/h$ |      | $k = \frac{\cos \theta}{8} \left( 1 + \frac{\tan \theta}{b/h} \right) - \frac{\cos \theta}{12(b/h)^2} \left( 1 + \frac{\cot^2 \theta}{2} \right)$ siendo $\cot \theta \leq b/h$ |      |      |      |      |      |      |      |      |      |      |      |                         |
|--|------|---|------|------|------|------|------|------|------|------|------|------|------|-------------------------|
| $b/h \backslash \theta$  | 5°   | 10°   | 15°  | 20°  | 30°  | 40°  | 45°  | 50°  | 60°  | 70°  | 75°  | 80°  | 90°  | $\theta \backslash b/h$ |

| 0,2  | 0,00 | 0,00  | 0,00 | 0,01 | 0,01 | 0,01 | 0,02 | 0,02 | 0,04 | 0,07 | 0,13 | 0,27 | 0,63 | 0,2                     |
| 0,1  | 0,00 | 0,00  | 0,00 | 0,00 | 0,00 | 0,01 | 0,01 | 0,01 | 0,01 | 0,04 | 0,06 | 0,14 | 1,25 | 0,1                     |

El desplazamiento mínimo del buque es igual al peso en rosca del buque, que recordamos es, aproximadamente, 1600 toneladas

Entonces,  $PR=1600t=\Delta_{min}$

## **6.1 Evaluación de corrección por superficies libres en los diferentes tanques**

Se adjunta tabla con los datos y resultados de todos los tanques:

|                      | PESO (t) | VOLUMEN (M3) | MANGA (B) | ALTURA (H) | ESLORA (L) | DENSIDAD | CB    | B/H   | K     | Msl 1 tanque | Msl parejas tanques | 1% dePR | Corrige |

**Tabla 2: Momentos de los tanques que sí corrigen**

A la hora de evaluar qué tanques corrigen y en qué situación lo hacen, es importante tener en cuenta los siguientes criterios:

-Se considera que un tanque de consumos (no lastre) corrige si sale de puerto y llega a caladero con una variación de volumen, si entra y sale de caladero con distinto volumen, o si sale de caladero y llega a puerto con distinto volumen.

-De entre los tanques de corrijan, se escogerá el más desfavorable de cada consumidor. Si se llenan o vacían los dos tanques de lastre de una condición a otra, corrigen ambos.

-El orden de consumo de combustible, que aparecerá en el libro de estabilidad del buque (a disposición del capitán), será el siguiente:

MDO3-MDO2-MDO1-MDO4-SEDIMENTACIÓN MDO-DIARIO MDO  
HFO3-HFO1-HFO2-HFO4-SEDIMENTACIÓN HFO-DIARIO HFO

Se exponen supuestas situaciones para ejemplificar estos criterios:

Los tanques de lastre corregirán siempre que se modifique su volumen entre dos condiciones, es decir, si el buque sale de puerto con el pique de popa y el de proa llenos, y llega a caladero con ellos vacíos, corregirán ambos.

Para los consumos, corregirán aquellos tanques que sean el peor de su grupo, es decir, de MDO corregirán los tanques MDO 2ER y 2BR, ya que son los que tienen mayor momento; si no se modifica su volumen entre 2 condiciones, corregirán los siguientes peores (MDO 4). Lo mismo ocurrirá con el grupo de HFO. Ocurriría lo mismo con los tanques de agua dulce, aguas negras, etc si corrigiesen, pero no es el caso.

Entonces, evaluamos en qué condiciones corrige cada tanque:

1-De la condición 1 a la condición 2, es decir, desde salida de puerto a la llegada a caladero:

El pique de proa sale al 0% y llega lleno y el pique de popa sale lleno y llega vacío, por lo que corregirán los tanques simétricos del pique de popa y el pique de proa en las dos condiciones.

Se modifica el volumen de MDO 2 y MDO 3, por lo que corregirán los tanques simétricos de MDO 2, que son los más desfavorables, en las condiciones 1 y 2.

Se modifica el volumen del tanque HFO 3, por lo que se aplican las correcciones por superficies libres en estos tanques simétricos en ambas condiciones.

2-De la llegada a caladero a la salida de caladero con las bodegas llenas, es decir, de la condición 2 a la condición 3:

El buque llega a puerto con el pique de popa vacío y lo llena, y el pique de proa que llega vacío, se llena antes de salir del caladero con las bodegas llenas, por lo tanto, los 3 tanques corrigen en ambas situaciones.

De la condición 2 a la condición 3, varía el volumen de los tanques MDO 1, MDO 2 y MDO 4, siendo el tanque de MDO 2 el que mayor corrección por superficies libres presenta.

Se consumen, y por tanto vacían, los tanques HFO 1, HFO 2 y HFO 3, por lo tanto, corregirá el tanque HFO 3 en las condiciones 2 y 3.

3- De la llegada a caladero a la salida de caladero con las bodegas al 20%, es decir, de la condición 2 a la condición 4:

El pique de proa se mantiene lleno, y el pique de popa sigue estando vacío, por lo que no corrigen.

Se consumen los tanques MDO 1, MDO2, MDO 3 y parcialmente MDO 4, por lo que corregirá el tanque MDO 2, que en la condición 2 iba mediado y es la peor de las correcciones.

De HFO acaban vacíos los tanques 1, 2, 3, y el 4 va al 80% de su capacidad, por lo tanto, corrige el tanque de HFO 3, que en la condición anterior iba al 30%.

4-De salida de caladero con bodegas llenas (condición 3) a llegada a puerto con bodegas llenas (condición 5):

En la condición 3 tenemos el pique de popa lleno y el de proa vacío, y en la condición 5 también, por lo que no se aplica corrección alguna.

Los tanques de MDO 4 salen mediados y se consumen de todo, y los de sedimentación están llenos en la condición 3 y llegan vacíos a la condición 4. Los otros tanques salen y llegan vacíos, por lo que corrige el tanque MDO 4, por ser el más desfavorable.

Varía el volumen solamente en los tanques HFO 4, por lo que será este el que corrija.

5-De salida de caladero con bodegas al 20% (condición 4) a llegada a puerto con bodegas al 20% (condición 6):

En la condición de salida de caladero el pique de proa está lleno al 100%, y el de popa vacío, a su llegada a puerto la condición es exactamente la misma, por lo que no corrigen los tanques de lastre.

Se vacían los tanques MDO 4 y sedimentación MDO, por lo que corregirá el tanque MDO 4.

Se modifica el volumen en el tanque de HFO 4, por lo que será este el que corrija.

Se adjunta una tabla con los tanques que corrigen en cada condición, aceptando la peor de las situaciones que acabamos de explicar:

|                      | Condición 1 | Condición 2 | Condición 3 | Condición 4 | Condición 5 | Condición 6 |

**Tabla 3: Tanques que corrigen en cada condición (los más desfavorables)**

## 7 CONDICIONES DE CARGA

### 7.1 Condición 1: salida de puerto con 100% consumos y 0% pesca

En esta condición, las capacidades de los tanques y bodegas serán las siguientes:

-Las bodegas irán totalmente vacías

-Todos los consumos irán al 100% de su capacidad, lo que quiere decir que todos los tanques de MDO y HFO estarán llenos, los tanques de agua dulce al 100% y los tanques de aceite lubricante al 100% también.

-Los tanques de aguas negras y lodos irán vacíos.

-El peso de los víveres será igual al total de esta partida, ya que el buque sale de puerto con las gambuzas llenas.

Adjuntamos imagen de esta condición introducida en Maxsurf:

## 7.2 Condición 2: Llegada a caladero con 70% consumos y 0% pesca

En esta condición tendremos el pique de proa lleno, para corregir el asiento, y el pique de popa vacío.

Recordamos que los tanques de MDO y HFO se consumen según el siguiente orden:

MDO3-MDO2-MDO1-MDO4-SEDIMENTACIÓN MDO-DIARIO MDO

HFO3-HFO1-HFO2-HFO4-SEDIMENTACIÓN HFO-DIARIO HFO

Decir también que se consumirán los tanques simétricos de manera sincronizada, de forma que siempre tengan la misma capacidad a babor y a estribor.

Entonces, en la condición 2 los tanques de MDO 3 ya están vacíos y los de MDO 2 están al 55%, para hacer así un 70,9% de la capacidad total de MDO.

De HFO se consume del tanque HFO 3, de manera que su capacidad en este momento es del 30%, y el total de HFO está en 70,4%

El agua dulce y el aceite están al 70% de su capacidad máxima, y las aguas negras y lodos al 30%.

Se adjunta captura de Maxsurf:

### 7.3 Condición 3: salida de caladero con 35% consumos y 100% pesca

Esta condición se dará tras una buena marea, y el buque saldrá del caladero con los el combustible, agua y aceite al 35% de la capacidad máxima, y los tanques de lodos y aguas negras ya estarán al 65%. En teoría el buque sale de caladero con el 100% de la capacidad de bodegas, pero en realidad, como hemos explicado antes en la partida correspondiente a las bodegas, no podemos llenar las bodegas al 100%, porque no sería realista, ya que tenemos troncos de escaleras, montacargas, carretillas, etc.

Entonces, la bodega principal irá al 85% de su capacidad, que es la máxima real. Y una vez llena esta bodega se llena la bodega de entrepuente, al 85% de su capacidad también, resultando entonces un volumen final de bodegas de 1517,6m3, que cumple la RPA del buque proyecto.

Adjuntamos captura de las diferentes partidas y sus capacidades de llenado:

## 7.4 Condición 4: salida de caladero con 35% consumos y 20% pesca

Esta condición es similar a la anterior: los tanques de consumos tendrán exactamente las mismas capacidades, pero las bodegas irán solamente al 20% de su capacidad, lo que quiere decir que llenamos la bodega principal hasta el 25%, para así alcanzar el 20% del volumen total de bodegas.

Será la situación que se de tras una mala marea, cuando el buque haya pasado los 25 días en caladero y vuelva a puerto con poca pesca.

Adjuntamos capturas de Maxsurf:

## 7.6 Condición 6: llegada a puerto con 10% consumos y 20% pesca

Es la condición que sigue a la 4: el barco sale de caladero tras una mala marea con las bodegas al 20% de su capacidad, y llega a puerto con el 10% de los consumos tras los 40 días de autonomía.

Los tanques de combustible, el aceite y el agua dulce van al 10% de su capacidad, y los tanques de aguas negras y lodos, al 90%.

De lastre no se modifican las condiciones de salida de caladero: pique de popa vacío y pique de proa a rebosar.

Podemos comprobarlo en la siguiente captura:

## 8 TABLA RESUMEN DE CONDICIONES DE CARGA

Todos los resultados de condiciones de carga obtenidos de Maxsurf se anexan al final del cuaderno, pero en este apartado se propone una tabla a modo de resumen para que sea más sencillo comparar resultados y verificar su corrección.

Entonces, en la siguiente tabla tenemos un resumen de los resultados de equilibrio tras el estudio de cada condición de carga:

|   | CONDICIÓN<br>1 | CONDICIÓN<br>2 | CONDICIÓN<br>3 | CONDICIÓN<br>4 | CONDICIÓN<br>5 | CONDICIÓN<br>6 |
|---|----------------|----------------|----------------|----------------|----------------|----------------|
| Draft Amidships m                       | 4,51           | 4,141          | 4,791          | 3,942          | 4,983          | 3,771          |

## **9 TABLA RESUMEN CRITERIOS ESTABILIDAD**

Al igual que en el apartado anterior hicimos una tabla para recoger todos los resultados de las condiciones de carga, en este apartado haremos una tabla con los resultados de los criterios de estabilidad y de viento para todas las condiciones. Aparecen en los reportes de Maxsurf anexados al final del cuaderno, aquí solamente se pretende facilitar su búsqueda.

## 10 COMENTARIOS FINALES A CONDICIONES DE CARGA Y ESTABILIDAD

Como comentarios finales, cabe señalar, que en ninguna condición de carga se ha alcanzado el calado máximo de verano 6,43m, calculado en el cuaderno 9, lo cual es bueno, ya que no superamos el francobordo del buque. De hecho, el calado máximo al que navegaremos será de 4,98m, por lo que tenemos algo más de un metro de reserva de flotabilidad.

Sobre los criterios de estabilidad y de viento lo único que tenemos que decir es que se cumplen en todas las condiciones, por lo que no hay problema.

En cuanto al trimado, las recomendaciones a seguir son que no exceda el 1,5% de la eslora entre perpendiculares de nuestro buque, 0,915m, y, como podemos ver en la tabla anterior, hay condiciones de carga en las que sobrepasamos este límite. El máximo alcanzado, en la condición 2, será de 1,95m, es decir, el 3% de la eslora entre perpendiculares. En esta condición, en un momento puntual, el buque llega al caladero con los consumos al 70% y las bodegas totalmente vacías, por lo que es normal que el buque tenga asiento por popa, porque las bodegas que están hacia proa están completamente vacías.

De todas formas, los asientos que exceden el límite del 1,5%Lpp son asientos positivos, por lo que el barco irá en empopado y la hélice siempre estará bajo el agua. Debería preocuparnos más el caso contrario, en el que asentase por proa y excediese los 0,9m.

En esta fase del proyecto la solución es complicada, ya que pasaría por rediseñar los tanques y compartimentos del buque. Una solución podría ser aumentar el tamaño de la bodega de entrepuente, quitándoselo a la planta de procesado, que en principio no tiene problemas de espacio. Al aumentar el volumen de la bodega de entrepuente podríamos disminuir el espacio de la bodega principal y así disponer de un tanque contiguo al HFO 1 o al HFO 3. Almacenaríamos en este nuevo tanque un combustible que dejaría de estar en los tanques de doble fondo, y entonces podríamos utilizar estos tanques de doble fondo, sobre todo los situados a proa, como tanques de lastre para corregir el asiento.

Como hemos visto en el cuaderno 4, los tanques de consumos están algo sobredimensionados, por lo que podríamos diseñar unos tanques más pequeños, que se ajusten a las capacidades mínimas, y así dejar sitio a proa para meter tanques de lastre que permitan corregir el trimado.

Otra posibilidad sería aumentar la altura del doble fondo del buque, y que en lugar de ser 1,5m en la zona de las bodegas fuese 2 por ejemplo, y este volumen que restaríamos a la bodega se compensaría con el aumento de la bodega de entrepuente.

Se ha contemplado la posibilidad de aumentar la bodega de entrepuente y disminuir la bodega principal, pero el hecho de disponer grandes pesos en la bodega de entrepuente perjudica gravemente a la estabilidad del buque, porque, al estar tan altos (de 6,6 a 9,4m), estos pesos originarían un gran par escorante, y dejaríamos de cumplir los criterios de estabilidad relativos a la escora.

Al tratarse de un buque pesquero, en el que el criterio económico tiene gran peso, decidimos minimizar los espacios “desaprovechados”, de manera que todos los tanques del buque son necesarios, o bien para consumos, o bien para deshechos. Reducir el espacio de bodegas para instalar tanques de lastre es una medida que no se contempló inicialmente ya que, al tratarse de un buque pesquero, cuanto más capacidad de bodegas tenga, más pescado puede almacenar, de manera que cada marea será más rentable y el buque se amortizará antes.

Sí que es cierto que la manera de optimizar el espacio útil de este buque pasaría por un rediseño de tanques y compartimentos, disponiendo tanques de combustible que se ajusten a las capacidades mínimas y no tan sobredimensionados como están ahora. Pero un rediseño estructural no tendría más objeto que la optimización y aprovechamiento del espacio y una ligera corrección del trimado, porque con los tanques y compartimentos que tenemos actualmente cumplimos las capacidades mínimas de consumos y bodegas, cumplimos con el calado máximo y con los criterios de estabilidad y de viento.
